## Submission to Ecology Letters

Dear Prof. Thrall,

Here we submit our manuscript, entitled: "On multiple infections by parasites with complex life cycles." for consideration for publication as a Letter in Ecology Letters. The draft conforms to the required specifications for the Letter format.

Parasites with complex life cycles traverse multiple hosts to complete their life cycles. They have, therefore, evolved various strategies to enable successful transmission, one of which is the famous host-manipulating ability. Trophically transmitted parasites are well known for modifying the behaviour of their intermediate hosts such that the predation rate by their definitive hosts increases, resulting in higher transmission rates from intermediate to definitive hosts. Interestingly, such manipulative ability changes when multiple parasites infect a host. For instance, predation rates may increase if coinfecting parasites are ready to transmit. On the other hand, if some parasites are still in their developmental phase and not yet ready to transmit, suppression of the predation rate may be more beneficial. When interests among coinfecting parasites clash, one group may win and dominate the manipulative outcomes.

In this manuscript, we use a mathematical model to study the effect of host manipulation on the ecological dynamics of a trophically transmitted parasite. We introduce multiple infections into the system, which has been studied thoroughly in virulence but not so extensively in trophically transmitted parasites. We also incorporate the parasite's free-living state, making our model more realistic than previous models. We focus on host manipulation in intermediate hosts, where effective manipulation results in higher predation rates and, thus, higher transmission rates from intermediate hosts to definitive hosts. Coinfecting parasites can cooperate and boost host manipulation, Nevertheless, they could also sabotage each other and decrease host manipulation.

new results!!

Our model shows the importance of considering multiple infections, which is a norm in nature rather than an exception. We also show that the free-living state of the parasite may have significant implications on the ecological dynamics. This novel result helps us understand the dynamics of parasites with complex lifecycles and their multi-host interactions in-depth. Our model addresses the gap in theoretical studies of trophically transmitted parasites, and we believe that our results are of interest to the readership of Ecology Letters.

We thank you for taking the time to consider our manuscript, and we look forward to your response.

With kind regards on behalf of the authors,

Chaitanya S. Gokhale
